# Hypercubes (or Butterfly)

More than networking topology, it is a data layout/partitioning strategy that let's you navigate your space in a predictive (and thus programmatic) fashion

## Navigating in this space

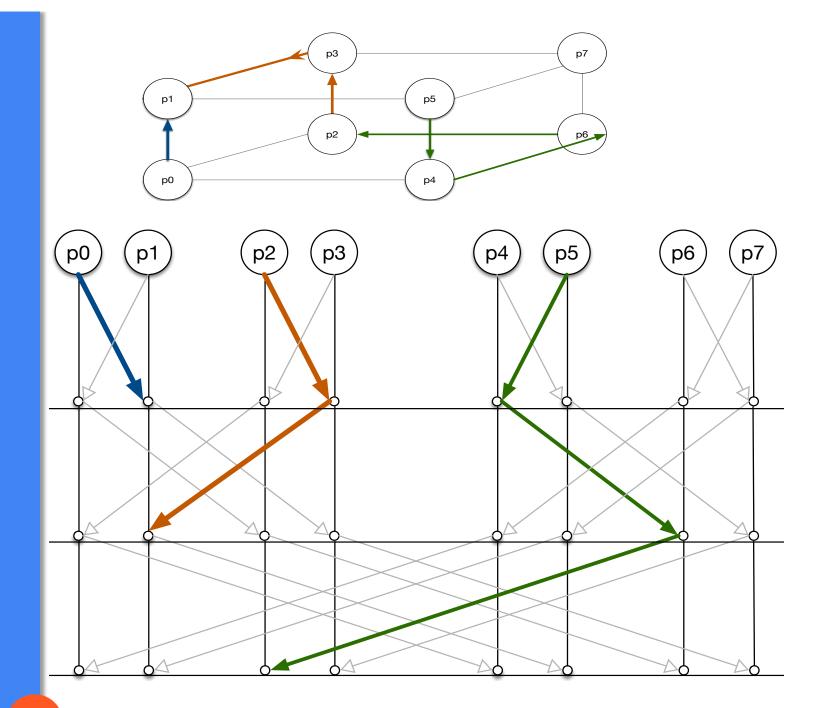

Say you want to move from:

 $P0 \rightarrow P1$  (in blue)

P2 → P3 (in orange)

P5 → P2 (in green)

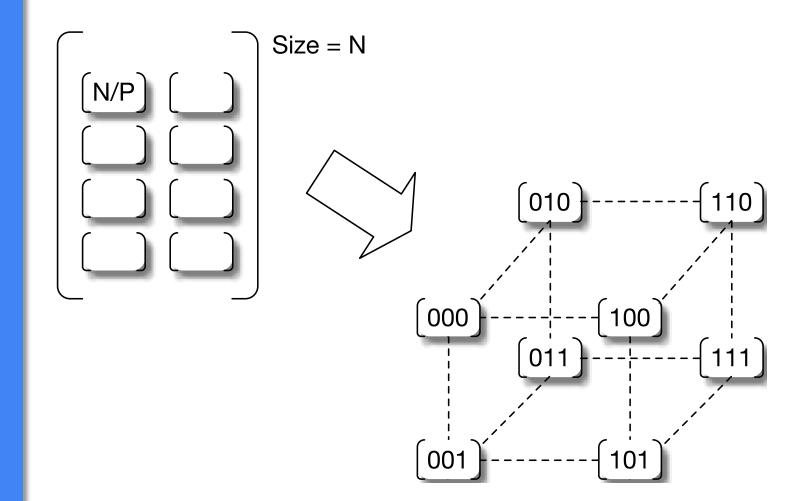

#### 0. Setup

- N elements
- $P = 2^d \text{ nodes}$

Step 1 → Distribute data amongst all nodes

Each node  $\rightarrow$  N/P elements

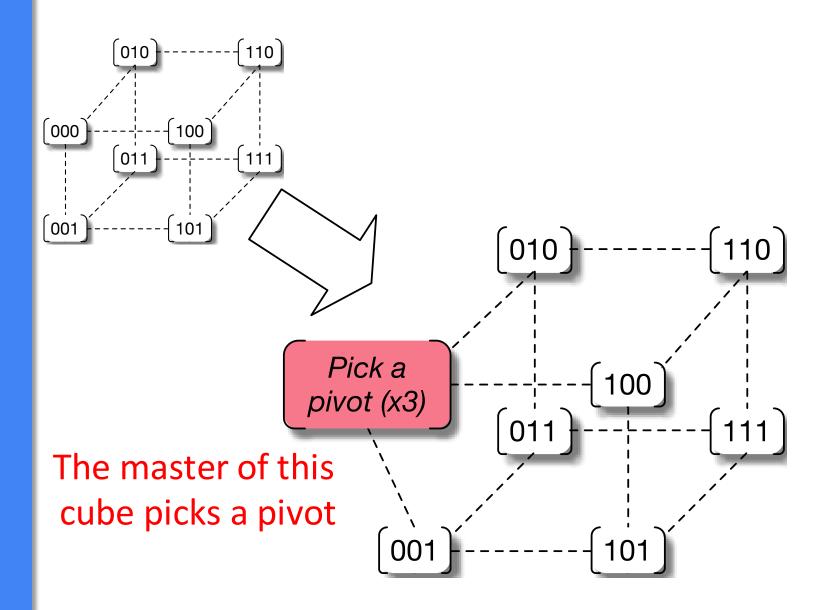

#### Master-of-thecube

Master > Responsible for starting the sequence of events that happen in the hypercube.

As you split the hypercube (i.e. process lower dimension hypercubes, each of those dimensions will have their own

Dimension	Master of Cube
3D	000
2D	x00 (i.e. 000 & 100 are the masters of their respective subcubes)
1D	xx0

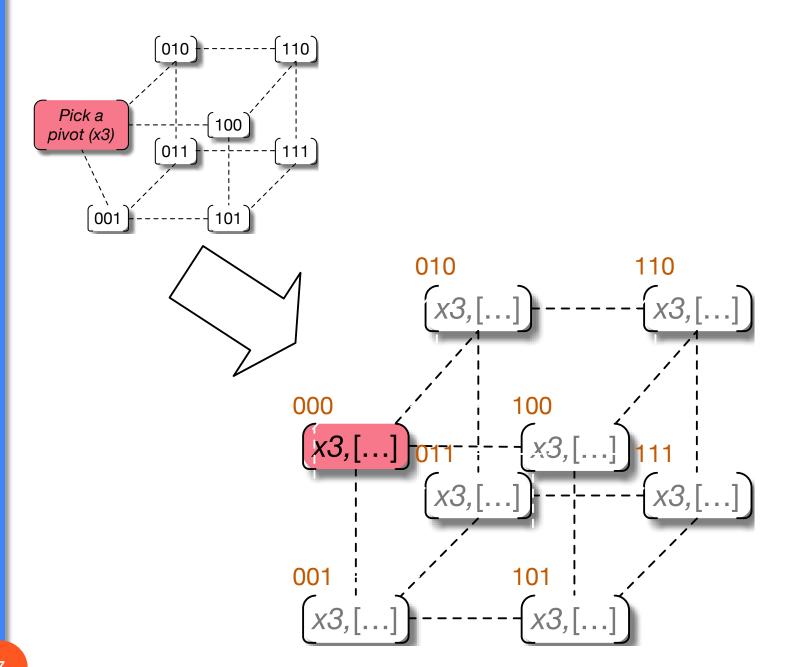

## Picking a Pivot

Bad choice of pivot at early stages degrades the performance significantly (no recovery from it). Use the average value elements in the *master-of-the-cube* as a pivot.

#### 1. Broadcast Pivot

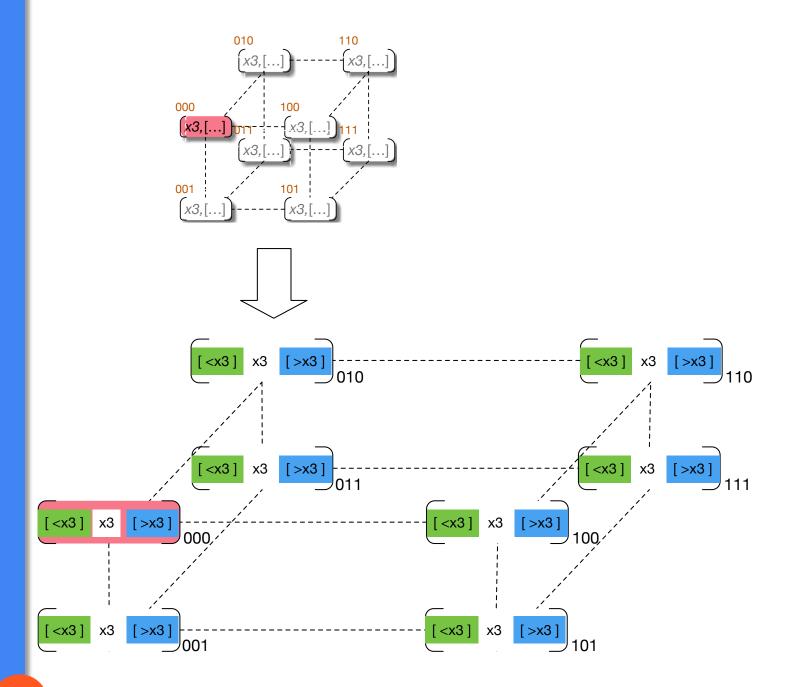

1. Master-of-thecube broadcasts pivot to all other nodes in the cube

2. Now all nodes have the pivot value

#### 2. In Each node...

1. Split the elements so that they are either greater than or less than the pivot (x3)

# 3. On the d<sup>th</sup> dimension exchange data

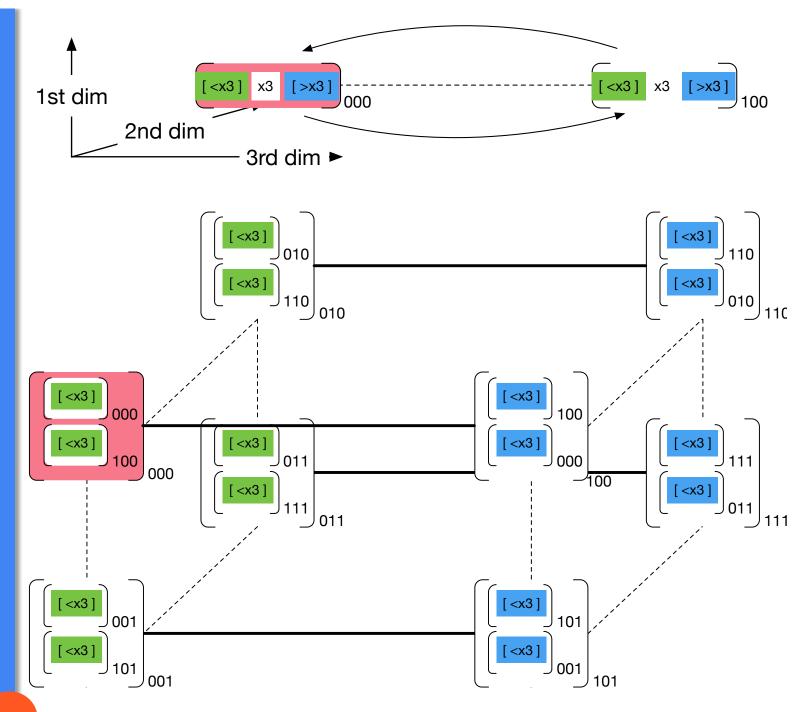

In step 1, d = 3

So we will exchange data on the 3<sup>rd</sup> dimension. i.e., we will exchange data between 0xx and 1xx

→ y0x and y1x (level 2)

→ yy0 and yy1 (level 3)

After the exchange, discard the pivot

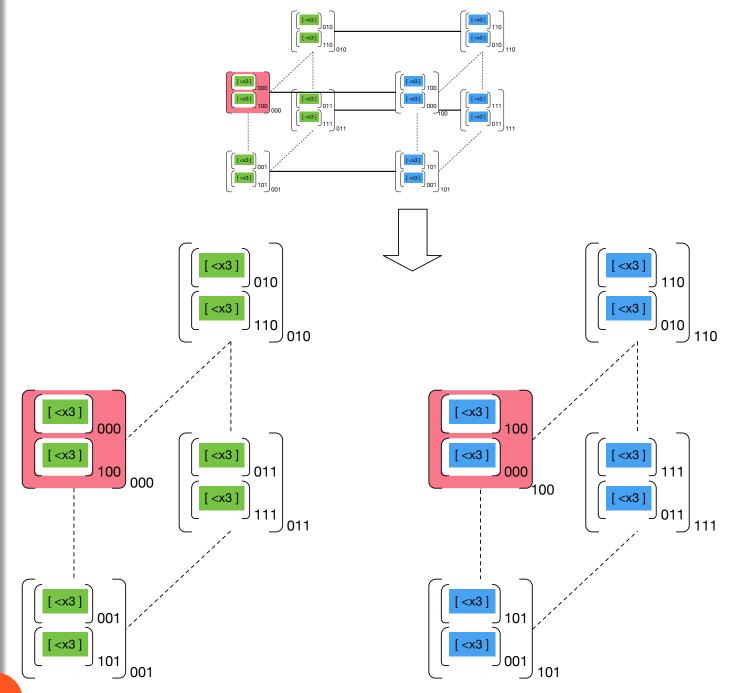

### 4. Let's split in to 2 d-1 cubes

In step 1, d = 3

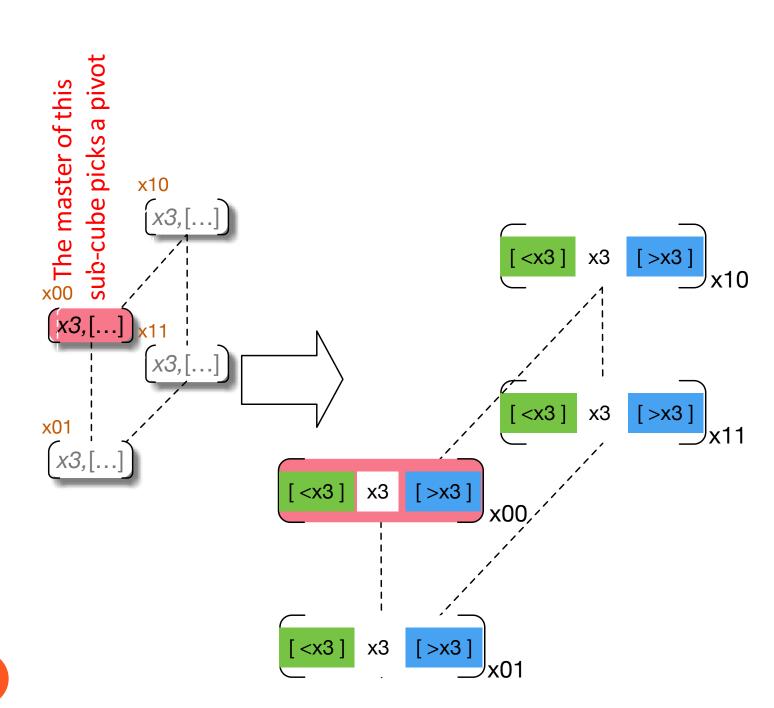

So we will exchange data on the 3<sup>rd</sup> dimension. i.e., we will exchange data between 0xx and 1xx

After the exchange, discard the pivot

Select new masters of the 2 sub-cubes

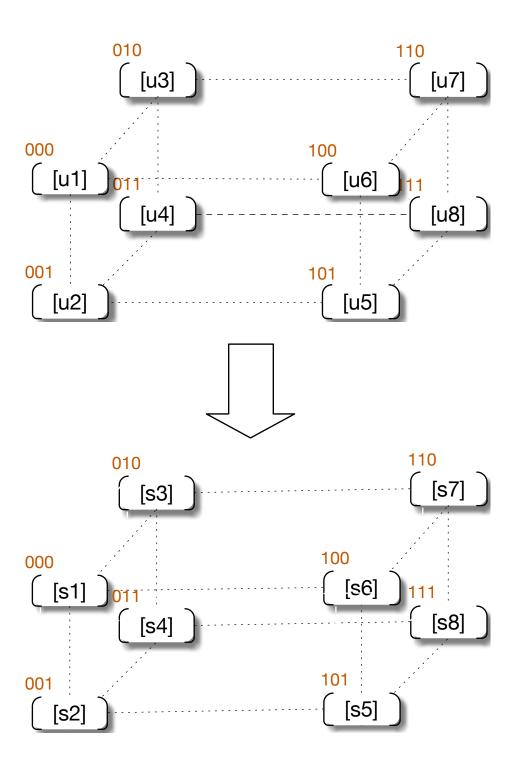

# 5. Repeat until you reach 1D cubes

Once you reach 1D subcubes, you have your elements chunked into 2<sup>d</sup> sorted sets

Apply quicksort on each of the chunks

S -> sorted version of an unsorted chunk U

## → All to One Reduce → 000 will get sorted numbers

#### Complexity Analysis

```
for L := dimension downto 1 | ogp
begin
  if master then
     choose a pivot value for the L-dimensional subcube; 1/p
  broadcast the pivot from the master to the subcube members; [1,logp]
  partition list[0:n<sub>element</sub>-1] into two sublists such that n/p
  list[0:j] ≤ pivot < list[j+1:n<sub>element</sub>-1];
  if lower partner then
T_{\text{average}} = O\left(\frac{n}{n}\log\frac{n}{n}\right) + O\left(\frac{n}{n}\log p\right) + O\left(\log^2 p\right) to partner;
  else if higher partner then
     begin
       send the left sublist list[0:j] to partner;
                                                                  n/p
       receive the right sublist of partner;
     end
  n_{\text{element}} := n_{\text{element}} - n_{\text{send}} + n_{\text{receive}};
end
sequential quicksort to list[0:n<sub>element</sub>-1] (n/p)log(n/p)
```
